Official Memorandum.

1923

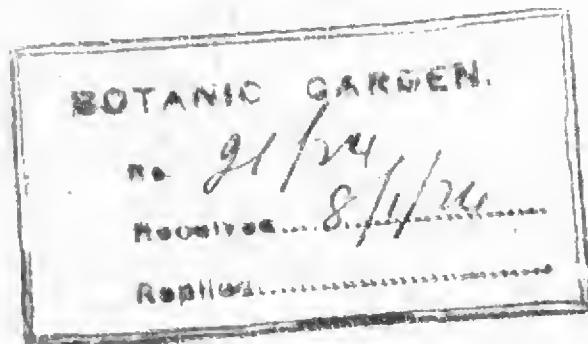

From _____

To Director, Botanic Gardens,
Singapore.

Dear Bunkill;

Herewith a copy of a report which I am sending to all State Forest Officers. It is chiefly remarkable as showing how very meagre our collections have been

F. W. Foxworthy

Dec. 29, 1923.

This term (which is contracted from phenomenology) is defined as, "The science of the relations between climate and periodic biological phenomena, as the migration and breeding of birds, the flowering and fruiting of plants, etc." The term makes a convenient single word reference for our records of the flowering and fruiting times of the different trees and it is proposed to use it as a heading in our files.

2. The Department has been accumulating phenological data for a number of years and a separate register has been kept in which were recorded the notes on flowering and fruiting that were given in forest officers' diaries. A considerably larger amount of information has been found on the field labels accompanying herbarium collections. The time of flowering and fruiting of particular trees may have considerable significance in Silviculture and we have been trying to gather such information for inclusion in descriptions of the different commercial timber trees.

3. Table No.1 has been prepared to include all of our authentic records of the time of flowering and fruiting of our timber trees in different years. The trees included in the timber roll are the principal ones considered. Mengkulang has been added because it is a tree which produces a timber of useful quality and in some quantity, and Tualang, because it is so conspicuous a feature of the landscape, in many places, and is a tree of some popular interest, by reason of its imposing appearance and large size. Much of the largest number of entries in the table have been taken from herbarium collections and represent fully opened flowers and mature fruit. No entry has been made in cases where the stage of flower or fruit development could not be determined.

TABLE No.1
TABLE OF FLOWERING AND FRUITING TIMES.

The most outstanding feature of this table is the distribution of flowering and fruiting times throughout the year and the apparent lack of definite flowering and fruiting seasons. The average number of entries for all forms in the table is a little more than six months for flowering and a little more than 6 months for fruiting. In several cases, as Damar Laut, Damar Hitam, Selimbar, Kumus, and Tualang, there are very few entries because there has been very little collecting of these forms; otherwise, the average number of entries would be larger. Kelat, Keruing, Nedang, Hempening, and Meranti have been collected in flower and in fruit in every month of the year, and a number of others have been collected in nearly every month. Most of these names represent a group of species, but Chengal, which is one species, has been collected in fruit in every month of the year and in flower in every month but January. There are 364 entries of flowering and 363 of fruiting. A separate tabulation by months has been made to see if that would give any indication of seasons. -

Month	Flower entries	Fruit entries	Total
January	22	24	46
February	27	26	53
March	32	22	54
April	36	20	56
May	41	33	74
June	38	28	66
July	28	33	61
August	32	47	79
September	32	35	67
October	30	34	64
November	19	26	45
December	27	37	64
	364	363	727

From this it would seem that May is the greatest month for flower and August for fruit. This is probably due to the entries from the east coast, where the seasons are more marked. The average number of entries per month is just over 60, and the only months which fall far below this number are January and November. There does not seem enough evidence here to warrant the conclusion that there are any sharply marked seasons.

4. A separate table, No. 2, has been prepared to show the records for 1923 and the places from which the records come. The reports have been made principally by this office and by the Forest Departments in Johore and Kedah.

Perak South	4		
(Chikus Res.)			

Doubtless the record would show a much larger number of entries if more people had been making observations. As it stands, it can only be assumed to be a very partial record of what has happened. It, however, shows that Keruing has been found in fruit ~~in~~ during every month of the year, Meranti in nine months, and Chengal in eight months. Chengal represents a single species.

5. In order to show how the records appear when applied to particular species, the following table, No. 3, has been prepared to show the records for 1923 of certain of the better known species of Meranti.

TABLE 3.
FLOWERING AND FRUITING OF CERTAIN OF THE COMMONER
SPECIES OF MERANTI DURING 1923.

SPECIES	: Month:	Flower	: Month:	Fruit
		Place		Place
MERANTI				
M. RAMBAI DAUN	: April	: Ulu Langat	:	:
S. acuminata	: June	: Kuantan	:	:
M. PA-ANG	: Jan.	: Dindings	: March	: Dindings

	: May	: Johore, Sungai Buloh	: Oct.	: Ginting Simpah, Chikus Res., Perak
	: Sept.	: Chikus Res., Perak	: Nov.	: Sungai Buloh, Kuala Kangsar.
	: Oct.	: " " "	: Dec.	: Sungai Buloh, Seremban.
MELANTAI				
	: April	: Kuantan	: Feb.	: Kanching
S. macroptera	:	:	: May	: Johore
			: June	: Kuantan, Johore.
			: July	: Johore
			: Aug.	: Kuantan, Kuala Lipis.
M. TEMBAGA	: June	: Kuantan	: May	: Johore
S. leprosula	: July	: Johore	: July	: Johore
	: Sept.	: Sungai Buloh	: Aug.	: Kuantan, Kuala Lipis
	: Nov.	: Sungai Buloh	: Oct.	: Ginting Simpah
			: Nov.	: Sungai Buloh.
M. SARANG PUNAI	: Oct.	: Sungai Buloh	: May	: Johore
S. parvifolia			: June	: Johore, Sungai Buloh
			: Nov.	: Kuala Kangsar, Kuala Lumpur, Sungai Buloh.

It is apparent from this table that the fruiting season has not been sharply marked in all cases. During August there was very pronounced fruiting of a number of species of Meranti and Keruing in eastern Pahang, but the same species were not apparently in either flower or fruit at that time in parts of the west coast. Some trees of Meranti Pa-ang and Meranti Sarang Punai fruited at Sungai Buloh in June and other trees of the same species during November or December. I am inclined to believe

I believe that the very local fruiting which is sometimes observed on the west coast is correlated with the very local distribution of rainfall. It seems that a more or less prolonged dry period followed by a warm soaking rain will bring a number of trees into flower, whatever the time of the year. Flowering is so very local that different trees of the same species and growing only a few miles, or even a few hundred yards, apart may flower and fruit at times several months apart. Another thing brought out by this work is the extremely meagre information that we have. It is hoped that more extended observations will be made the coming year, so that we can prepare a much more representative phenological report at the end of the year. It is probable that nearly all of our species of timber trees will be found in flower during the year, if they are watched in every district.

6. Recommendations concerning future observations.

Reports should state whether flowering or fruiting seems to be general or sporadic. Chengal has most often been observed to flower sporadically, only a fraction of the mature trees in a given area flowering at one time, while Kapur has more often been observed in general flower, although there have been observations made when it was only flowering sporadically.

It would be very useful if State Forest Officers would require reports of flowering or fruiting of the principal species from each of their districts. This might help us to determine whether there are any general rules governing the occurrence of flower and fruit in particular places.
